# Blind No More = GRAY BOX Optimization 

Darrell Whitley<br>Computer Science, Colorado State University

With Thanks to: Francisco Chicano, Gabriela Ochoa, Andrew Sutton and Renato Tinós

## GRAY BOX OPTIMIZATION

We can construct "Gray Box" optimization for pseudo-Boolean optimization problems composed of $M$ subfunctions, where each subfunction accepts at most $k$ variables.

Exploit the general properties of every Mk Landscape:

$$
f(x)=\sum_{i=1}^{m} f_{i}(x)
$$

Which can be expressed as a Walsh Polynomial

$$
W(f(x))=\sum_{i=1}^{m} W\left(f_{i}(x)\right)
$$

Or can be expressed as a sum of $k$ Elementary Landscapes

$$
f(x)=\sum_{i=1}^{k} \varphi^{(k)}(W(f(x)))
$$

## Walsh Example: MAXSAT

Given a logical expression consisting of Boolean variables, determine whether or not there is a setting for the variables that makes the expression TRUE.

Literal: a variable or the negation of a variable
Clause: a disjunct of literals

$$
\begin{gathered}
\text { A 3SAT Example } \\
\left(\neg x_{2} \vee x_{1} \vee x_{0}\right) \wedge\left(x_{3} \vee \neg x_{2} \vee x_{1}\right) \wedge\left(x_{3} \vee \neg x_{1} \vee \neg x_{0}\right) \\
\text { recast as a MAX3SAT Example } \\
\left(\neg x_{2} \vee x_{1} \vee x_{0}\right)+\left(x_{3} \vee \neg x_{2} \vee x_{1}\right)+\left(x_{3} \vee \neg x_{1} \vee \neg x_{0}\right)
\end{gathered}
$$

## Walsh Example

$$
\frac{1}{8}\left[\begin{array}{l}
1 \\
1 \\
1 \\
1 \\
0 \\
1 \\
1 \\
1
\end{array}\right]^{\top}\left[\begin{array}{rrrrrrrr}
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\
1 & 1 & -1 & -1 & 1 & 1 & -1 & -1 \\
1 & -1 & -1 & 1 & 1 & -1 & -1 & 1 \\
1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\
1 & -1 & 1 & -1 & -1 & 1 & -1 & 1 \\
1 & 1 & -1 & -1 & -1 & -1 & 1 & 1 \\
1 & -1 & -1 & 1 & -1 & 1 & 1 & -1
\end{array}\right]=\left[\begin{array}{r}
0.875 \\
-0.125 \\
-0.125 \\
-0.125 \\
0.125 \\
0.125 \\
0.125 \\
0.125
\end{array}\right]
$$

- All $\psi_{j}$ 's except $\psi_{0}$ have 41 's and $4-1$ 's.
- $\psi_{0}$ has all 1's.
- $\mathbf{f}$ for clauses of length 3 will contain one 0

## Walsh Example

$$
\begin{aligned}
& f_{1}=\left(\neg x_{2} \vee x_{1} \vee x_{0}\right) \\
& f_{2}=\left(x_{3} \vee \neg x_{2} \vee x_{1}\right) \\
& f_{3}=\left(x_{3} \vee \neg x_{1} \vee \neg x_{0}\right)
\end{aligned}
$$

| $x$ | $w_{i}$ | $W\left(f_{1}\right)$ | $W\left(f_{2}\right)$ | $W\left(f_{3}\right)$ | $W(f(x))$ |
| :--- | :--- | ---: | ---: | ---: | ---: |
| 0000 | $w_{0}$ | 0.875 | 0.875 | 0.875 | 2.625 |
| 0001 | $w_{1}$ | -0.125 | 0 | 0.125 | 0 |
| 0010 | $w_{2}$ | -0.125 | -0.125 | 0.125 | -0.125 |
| 0011 | $w_{3}$ | -0.125 | 0 | -0.125 | -0.250 |
| 0100 | $w_{4}$ | 0.125 | 0.125 | 0 | 0.250 |
| 0101 | $w_{5}$ | 0.125 | 0 | 0 | 0.125 |
| 0110 | $w_{6}$ | 0.125 | 0.125 | 0 | 0.250 |
| 0111 | $w_{7}$ | 0.125 | 0 | 0 | 0.125 |
| 1000 | $w_{8}$ | 0 | -0.125 | -0.125 | -0.250 |
| 1001 | $w_{9}$ | 0 | 0 | 0.125 | 0.125 |
| 1010 | $w_{10}$ | 0 | -0.125 | 0.125 | 0 |
| 1011 | $w_{11}$ | 0 | 0 | -0.125 | -0.125 |
| 1100 | $w_{12}$ | 0 | 0.125 | 0 | 0.125 |
| 1101 | $w_{13}$ | 0 | 0 | 0 | 0 |
| 1110 | $w_{14}$ | 0 | 0.125 | 0 | 0.125 |

## BLACK BOX OPTIMIZATION

Don't wear a blind fold when walking about London if you can help it!

## NK-Landscapes

An Adjacent NK Landscape: $n=6$ and $k=3$. The subfunctions:

$$
\begin{aligned}
& f_{0}\left(x_{0}, x_{1}, x_{2}\right) \\
& \qquad \begin{array}{l}
f_{1}\left(x_{1}, x_{2}, x_{3}\right) \\
\quad f_{2}\left(x_{2}, x_{3}, x_{4}\right) \\
f_{3}\left(x_{3}, x_{4}, x_{5}\right) \\
\quad f_{4}\left(x_{4}, x_{5}, x_{0}\right) \\
\quad f_{5}\left(x_{5}, x_{0}, x_{1}\right)
\end{array}
\end{aligned}
$$

These problems can be solved to optimality using Dynamic Programming.

## Percent of Offspring that are Local Optima

Using a Very Simple (Stupid) Hybrid GA:

| $N$ | $k$ | Model | 2-point Xover | Uniform Xover | PX |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 100 | 2 | Adj | $74.2 \pm 3.9$ | $0.3 \pm 0.3$ | $100.0 \pm 0.0$ |
| 300 | 4 | Adj | $30.7 \pm 2.8$ | $0.0 \pm 0.0$ | $94.4 \pm 4.3$ |
| 500 | 2 | Adj | $78.0 \pm 2.3$ | $0.0 \pm 0.0$ | $97.9 \pm 5.0$ |
| 500 | 4 | Adj | $31.0 \pm 2.5$ | $0.0 \pm 0.0$ | $93.8 \pm 4.0$ |
| 100 | 2 | Rand | $0.8 \pm 0.9$ | $0.5 \pm 0.5$ | $100.0 \pm 0.0$ |
| 300 | 4 | Rand | $0.0 \pm 0.0$ | $0.0 \pm 0.0$ | $86.4 \pm 17.1$ |
| 500 | 2 | Rand | $0.0 \pm 0.0$ | $0.0 \pm 0.0$ | $98.3 \pm 4.9$ |
| 500 | 4 | Rand | $0.0 \pm 0.0$ | $0.0 \pm 0.0$ | $83.6 \pm 16.8$ |

## Number of partition components discovered

| $N$ | $k$ | Model | Paired PX |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Mean | Max |
| 100 | 2 | Adjacent | $3.34 \pm 0.16$ | 16 |
| 300 | 4 | Adjacent | $5.24 \pm 0.10$ | 26 |
| 500 | 2 | Adjacent | $7.66 \pm 0.47$ | 55 |
| 500 | 4 | Adjacent | $7.52 \pm 0.16$ | 41 |
| 100 | 2 | Random | $3.22 \pm 0.16$ | 15 |
| 300 | 4 | Random | $2.41 \pm 0.04$ | 13 |
| 500 | 2 | Random | $6.98 \pm 0.47$ | 47 |
| 500 | 4 | Random | $2.46 \pm 0.05$ | 13 |

Paired PX uses Tournament Selection. The first parent is selected by fitness. The second parent is selected by Hamming Distance.

## Optimal Solutions for Adjacent NK

|  |  | 2-point | Uniform | Paired PX |
| :---: | :---: | :---: | :---: | :---: |
| $N$ | $k$ | Found | Found | Found |
| 300 | 2 | 18 | 0 | 100 |
| 300 | 3 | 0 | 0 | 100 |
| 300 | 4 | 0 | 0 | 98 |
| 500 | 2 | 0 | 0 | 100 |
| 500 | 3 | 0 | 0 | 98 |
| 500 | 4 | 0 | 0 | 70 |

Percentage over 50 runs where the global optimum was Found in the experiments of the hybrid GA with the Adjacent NK Landscape.

## Tunnelling Local Optima Networks

NK Landscapes: Ochoa et al. GECCO 2015

## NK and Mk Landscapes, P and NP

## NK and Mk Landscapes, P and NP

## But a Hybrid Genetic Algorithm is NOT how we should solve these NK Landscape Problems.

We can exactly know the location of improving moves in constant time. No enumeration of neighbors is needed.

Under well behaved conditions, we can exactly know the location of improving moves for $r$ steps ahead in constant time.

## Walsh Analysis

Every $n$-bit MAXSAT or NK-landscape or P-spin problem is a sum of $m$ subfunctions, $f_{i}$ :

$$
f(x)=\sum_{i=1}^{m} f_{i}(x)
$$

The Walsh transform of $f$ is a sum of the Walsh transforms of the individual subfunctions.

$$
W(f(x))=\sum_{i=1}^{m} W\left(f_{i}(x)\right)
$$

If $m$ is $O(n)$ then the number of Walsh coefficients is $m 2^{k}=O(n)$.

## "Mk Landscapes"

A General Model for all bounded Pseudo-Boolean Problems

## When 1 bit flips what happens?

## Constant Time Steepest Descent

Assume we flip bit $p$ to move from $x$ to $y_{p} \in N(x)$.
Construct a vector Score such that

$$
\operatorname{Score}\left(x, y_{p}\right)=-2\left\{\sum_{\forall b, p \subset b}-1^{b^{T} x} w_{b}(x)\right\}
$$

In this way, all of the Walsh coefficients whose signs will be changed by flipping bit $p$ are collected into a single number $\operatorname{Score}\left(x, y_{p}\right)$.

The GSAT algorithm has done this for 23 years (Thanks to H. Hoos).

NOTE: Hoos and Stützle have claimed a constant time result, but without proof. An average case complexity proof is required to obtain general constant time complexity results (Whitley 2013, AAAI). Also it does not matter if the problems are uniform random or not.

## Best Improving and Next Improving moves

"Best Improving" and "Next Improving" moves cost the same.

GSAT uses a Buffer of best improving moves

$$
\text { Buffer(best.improvement })=<M_{10}, M_{1919}, M_{9999}>
$$

But the Buffer does not empty monotonically: this leads to thrashing.
Instead uses multiple Buckets to hold improving moves

$$
\begin{gathered}
\text { Bucket(best.improvement })=<M_{10}, M_{1919}, M_{9999}> \\
\text { Bucket(best.improvement }-1)=<M_{8371}, M_{4321}, M_{847}> \\
\text { Bucket(all.other.improving.moves) }=<M_{40}, M_{519}, M_{6799}>
\end{gathered}
$$

This improves the runtime of GSAT by a factor of 20X to 30X. The solution for NK Landscapes is only slightly more complicated.

## The locations of the updates are obvious

$$
\begin{aligned}
& \operatorname{Score}\left(y_{p}, y_{1}\right)=\operatorname{Score}\left(x, y_{1}\right) \\
& \operatorname{Score}\left(y_{p}, y_{2}\right)=\operatorname{Score}\left(x, y_{2}\right) \\
& \operatorname{Score}\left(y_{p}, y_{3}\right)=\operatorname{Score}\left(x, y_{3}\right)-2\left(\sum_{\forall b,(p \wedge 3) \subset b} w_{b}^{\prime}(x)\right) \\
& \operatorname{Score}\left(y_{p}, y_{4}\right)=\operatorname{Score}\left(x, y_{4}\right) \\
& \operatorname{Score}\left(y_{p}, y_{5}\right)=\operatorname{Score}\left(x, y_{5}\right) \\
& \operatorname{Score}\left(y_{p}, y_{6}\right)=\operatorname{Score}\left(x, y_{6}\right) \\
& \operatorname{Score}\left(y_{p}, y_{7}\right)=\operatorname{Score}\left(x, y_{7}\right) \\
& \operatorname{Score}\left(y_{p}, y_{8}\right)=\operatorname{Score}\left(x, y_{8}\right)-2\left(\sum_{\forall b,(p \wedge 8) \subset b} w_{b}^{\prime}(x)\right) \\
& \operatorname{Score}\left(y_{p}, y_{9}\right)=\operatorname{Score}\left(x, y_{9}\right)
\end{aligned}
$$

## The locations of the updates are obvious

$$
\begin{aligned}
& S_{2}\left(y_{p}\right)=S_{2}(x) \\
& S_{3}\left(y_{p}\right)=S_{3}(x) \\
& S_{4}\left(y_{p}\right)=S_{4}(x) \\
& \left.S_{5}\left(y_{p}\right)=S_{5}(x)(x)-2 y_{p}\right)=S_{6}(x) \\
& S_{7}\left(y_{p}\right)=S_{7}(x)
\end{aligned}
$$

## What if we could look R Moves Lookahead?

Consider $\mathrm{R}=3$
Let $\operatorname{Score}\left(3, x, y_{i, j, k}\right)$ indicate we move from $x$ to $y_{i, j, k}$ by flipping the 3 bits $i, j, k$. In general, we compute $\operatorname{Score}\left(r, x, y_{p}\right)$ when flipping $r$ bits.

$$
\begin{aligned}
f\left(y_{i}\right) & =f(x)+\operatorname{Score}\left(1, x, y_{i}\right) \\
f\left(y_{i, j}\right) & =f\left(y_{i}\right)+\operatorname{Score}\left(1, y_{i}, y_{j}\right) \\
f\left(y_{i, j}\right) & =f(x)+\operatorname{Score}\left(2, x, y_{i, j}\right) \\
f\left(y_{i, j, k}\right) & =f\left(y_{i, j}\right)+\operatorname{Score}\left(1, y_{i, j}, y_{k}\right) \\
f\left(y_{i, j, k}\right) & =f(x)+\operatorname{Score}\left(3, x, y_{i, j, k}\right)
\end{aligned}
$$

With thanks to Francisco Chicano!

## Why Doesn't this exponentially EXPLODE???

$$
\begin{aligned}
f\left(y_{i, j, k}\right) & =\left(\left(f(x)+\operatorname{Score}\left(1, x, y_{i}\right)\right)+\operatorname{Score}\left(1, y_{i}, y_{j}\right)\right)+\operatorname{Score}\left(1, y_{i, j}, y_{k}\right) \\
\operatorname{Score}\left(3, x, y_{i, j, k}\right) & =\operatorname{Score}\left(2, x, y_{i, j}\right)+\operatorname{Score}\left(1, y_{i, j}, y_{i, j, k}\right)
\end{aligned}
$$

If there is no Walsh Coefficient $w_{i, j}$ then $\operatorname{Score}\left(1, y_{i}, y_{i, j}\right)=0$.
Assume we have already moves of length shorter than 3. If there are no Walsh Coefficients "linking" $i, j, k$ then $\operatorname{Score}\left(3, x, y_{i, j, k}\right)=0$.

## The Variable Interaction Graph

The Variable Interaction Graph
Assume all distance 1 moves are taken.
There cannot be a move flipping bits 4, 6, 9 that yields an improving move because there are no interactions and no Walsh coefficients.

## Multiple Step Lookahead Local Search

In this figure, $\mathrm{N}=12,000, \mathrm{k}=3$, and $\mathrm{q}=4$. The radius is $1,2,3,4,5,6$. At $r=6$ the global optimum is found.

## Steepest Descent on Moments

Both $f(x)$ and $\operatorname{Avg}(N(x))$ can be computed with Walsh Spans.

$$
\begin{gathered}
f(x)=\sum_{z=0}^{3} \varphi^{(z)}(x) \\
\operatorname{Avg}(N(x))=f(x)-1 / d \sum_{z=0}^{3} 2 z \varphi^{(p)}(x) \\
\operatorname{Avg}(N(x))=\sum_{z=0}^{3} \varphi^{(z)}(x)-1 / N \sum_{z=0}^{3} 2 z \varphi^{(z)}(x) \\
\operatorname{Avg}(N(x))=\sum_{z=0}^{3} \varphi^{(z)}(x)-2 / N \sum_{z=0}^{3} z \varphi^{(z)}(x)
\end{gathered}
$$

## Steepest Descent on Moments

Assume the vectors $S_{p}=S \operatorname{Score}_{p}$ and $Z_{p}$ just map the change in the Walsh coefficients. $Z_{p}$ is computed using changes in $z \varphi^{(z)}(x)$

```
\(\operatorname{ScoreAvg}\left(y_{p}, y_{1}\right)=\operatorname{ScoreAvg}\left(x, y_{1}\right)\)
\(\operatorname{ScoreAvg}\left(y_{p}, y_{2}\right)=\operatorname{ScoreAvg}\left(x, y_{2}\right)\)
ScoreAvg \(\left(y_{p}, y_{3}\right)=\operatorname{ScoreAvg}\left(x, y_{3}\right)+\) WeightedWalshUpdate
\(\operatorname{ScoreAvg}\left(y_{p}, y_{4}\right)=\operatorname{ScoreAvg}\left(x, y_{4}\right)\)
\(\operatorname{ScoreAvg}\left(y_{p}, y_{5}\right)=\operatorname{ScoreAvg}\left(x, y_{5}\right)\)
\(\operatorname{ScoreAvg}\left(y_{p}, y_{6}\right)=\operatorname{ScoreAvg}\left(x, y_{6}\right)\)
\(\operatorname{ScoreAvg}\left(y_{p}, y_{7}\right)=\operatorname{ScoreAvg}\left(x, y_{7}\right)\)
\(\operatorname{ScoreAvg}\left(y_{p}, y_{8}\right)=\operatorname{ScoreAvg}\left(x, y_{8}\right)+\) WeightedWalshUpdate
\(\operatorname{ScoreAvg}\left(y_{p}, y_{9}\right)=\operatorname{ScoreAvg}\left(x, y_{9}\right)\)
```

## $\Theta(1)$ Steepest Descent on Moments

$$
\begin{aligned}
U_{1}\left(y_{p}\right) & =U_{1}(x) \\
U_{2}\left(y_{p}\right) & =U_{2}(x) \\
U_{3}\left(y_{p}\right) & =U_{3}(x)+\text { Update } \\
U_{4}\left(y_{p}\right) & =U_{4}(x) \\
U_{5}\left(y_{p}\right) & =U_{5}(x) \\
U_{6}\left(y_{p}\right) & =U_{6}(x) \\
U_{7}\left(y_{p}\right) & =U_{7}(x) \\
U_{8}\left(y_{p}\right) & =U_{8}(x)+\text { Update } \\
U_{9}\left(y_{p}\right) & =U_{9}(x)
\end{aligned}
$$

## What's (Obviously) Next?

- Local Search with r Move Lookahead PLUS Partition Crossover.
- Apply r Move Lookahead and Partition Crossover to MAX-kSAT.
- Use Deterministic Improving Moves.
- Use Deterministic Recombination.

## What's (Obviously) Next?

We can now solve 1 million variable NK-Landscapes to optimality in approximately linear time. (Paper submitted.)

## What's (Obviously) Next?

- Put an End to the domination of Black Box Optimization.
- Wait for Tonight and Try to Take over the World.

## THANK YOU

Take Home Message:
PROBLEM STRUCTURE MATTERS.

Black Box Optimizers can never match the performance of an algorithm that efficiently exploits problem structure.

But we need only a small amount of information: Gray Box Optimization.

For Mk Landscapes, we can use
Deterministic Moves and Deterministic Crossover.
